

Best Practices for Standard Checkout Integration

Best practices for a smoother Standard Checkout web integration and payment experience.

Follow the best practices for a smooth Standard Checkout web integration.

Capture Payment Using Payment Capture Settings

You **must capture** the authorised payments for the **settlement of the payments** in your bank account. Use the

[Payment Capture Setting](#) to configure the capture settings at an account level via the Dashboard.

Integrate Orders API

Orders bind multiple payment attempts for a single order. This helps to **prevent multiple payments**.

[Integrate with Orders API](#) on your server-side and pass the `order_id` to Checkout.

Verify Signature to Avoid Data Tampering

This is a mandatory step to confirm the authenticity of the details returned to the Checkout form for successful payments. Know how to

[verify payment signature](#).

Check Payment/Order Status before Providing Services

Check the payment/order status, that is if the payment's status is `captured` and the order's status is `paid` before providing the services to the customers.

- [Fetch All Payments for an Order API](#)
- [Fetch Status of a Payment using Payment id API](#)
- [Fetch Status of an Order using Order id API](#)

Implement Webhooks

Implement webhooks or the query API to avoid callback failure (drop-offs could be due to connectivity or network failure) and to verify the payment details via an S2S call. Know more about

[Webhooks](#). You should enable the following webhooks:

- `payment.captured`
- `payment.failed`
- `order.paid`

Implement Callback URL

Sites like Instagram, Facebook Messenger, Opera and UC browser do not support i-frame. You should implement

[callback URL](#) if your customers use any of these for making payments.
